

Dashboard on Real, Complete Data

What changed from the earlier version

Earlier Day 3 dashboard used a single-day snapshot with my own per-grid CTBI calculation. This version uses **Garima's actual real output** (`priority_rubric_v1_full_test.csv`, produced via her Day 3 spatial integration + Khushi's Day 3 thermal-tier categorization) — the authoritative, team-validated dataset, not a placeholder.

Key upgrade: date selector

Garima's real data covers **all 546 days (2021–2026)**, not just one snapshot. Added a date slider so any day in the 6-year record can be explored — defaults to the peak CTBI day (May 23, 2025) for the most compelling first view, but the whole history is browsable.

What's real vs. pending (unchanged philosophy, now more precise)

● **Real:** 48 ward boundaries, CTBI/NCTL/UTCI for every ward on every day (546 days × 48 wards, zero missing values) ● **Pending:** vulnerability & response capacity — the dashboard labels priority as **"thermal-only, partial"**, using Khushi's exact wording from her own Day 3 output, so the whole team's messaging is consistent (dashboard, Decision Log, and Khushi's data file all say the same thing)

Honest finding carried through

Confirmed directly in the data: only **2 unique UTCI values** appear across all 48 wards on any given day (matches Garima's Day 3 finding — ERA5's ~25km resolution is coarser than Ahmedabad's ward scale). CTBI/NCTL are identical across all wards too (they're city-wide values, not per-grid, in Garima's join). This is documented, not hidden — the map's real differentiation currently comes from which wards happen to fall in the same ERA5 grid cell, not fine-grained local weather variation. Vulnerability data, once added, will be the layer that actually differentiates ward priority meaningfully.

Files produced

- `app.py` — dashboard with date selector, real 546-day data, honest pending-priority state

Handoff

- Once vulnerability data is manually obtained, only the priority calculation needs updating (swap the thermal-only label for Khushi's full rubric output) — no UI/architecture changes needed.
